Data Analysis with PsyR :: Cheatsheet

Getting Started

PsyR utilises procedures described by Bird (2002) to compute confidence intervals for planned and post-hoc contrasts from ANOVA models. PsyR uses functions from Afex and Emmeans to implement ANOVA models and obtain estimated marginal means

The following template demonstrates how to generate PsyR confidence intervals:

- Load data, tidy into longform
- Using afex::aov_ez(), generate an ANOVA model
- Using list(), define contrast in mean difference scaling
- Using emmeans::contrast(), generate hypothesis tests of desired contrasts
- Using PsyR::psyci(), generate simultaneous confidence intervals. To do so, place:
  - The ANOVA model in the "mod" argument
  - The table of lists of contrasts in the "contrast_tables" argument
  - The desired method as a string ("ind", "bf", "ph", or "smr") in the "method" argument
